## Introduction

This booklet's purpose is to explain the construction and operation of an interpreter for the COSMAC 1802 "ELF". It assumes that the reader has some knowledge of the 1802 instruction set and is able to write simple machine language programs. Mnemonics are not provided because most Elf owners do not have access to assemblers and must work directly in machine language. Instead, programs are explained in a documented, step-by-step fashion, that it is hoped will make the concepts involved easy to follow.

The interpretive language described is "CHIP-8", the language used by RCA Corporation in its "COSMAC VIP" computer. CHIP-8 is a simple language consisting of about 30 instructions. RCA's interpreter is elegant and well thought out; once understood it is easily changed and modified.

This booklet contains five sections; in the first section a simple demonstration interpreter is introduced. This demonstration interpreter runs in the basic ¼K "Elf" and its instructions are a subset of the full CHIP-8 instruction set. While simple, the demonstration interpreter employs methods similar to those used in the full interpreter.

Further sections discuss the full CHIP-8 instruction set, hardware differences between the "VIP" and the "ELF", and provide a listing of a complete ELF interpreter together with suggestions for implementing it on various machines. The final section discusses the extension of the CHIP-8 instruction set. Examples are provided for multiply and divide instructions together with an instruction which displays characters for the 64 six bit ASCII symbols.

I should like to thank RCA Corporation for permission to write about CHIP-8 and to modify it for the Elf. However RCA is not responsible for any of the material in this booklet. The programs described have been thoroughly tested on a number of versions of the COSMAC "ELF" as described in the Popular Electronics articles and are believed to be reliable but there is, of course, still the possibility that they contain unexpected errors. This kind of interpreter is rather hardware dependent and changes in input/output lines or in the use of flag lines will cause failures. An attempt was made to provide sufficient documentation so that the user can make the changes necessary to implement CHIP-8 on a variety of machines.

## A Demonstration Interpreter

The surprising power of computers is due to the development of languages which organize programming into different levels of complexity. Perhaps the simplest way to organize programming with a language is to use an interpreter. One can consider an interpreter to be a program that converts the basic instruction set to a new language, a set of instructions that better suits the programmer. Alternatively an interpreter can be thought of as a program with a control section and a number of subroutines, the new language now instructs the interpreter as to which subroutines to call and in which order. The subroutines perform "tasks" which are more complicated than those performed by a single machine code operation. The ubiquitous basic interpreter is a good example.

RCA's CHIP-8 language is an interpretive one and it converts the 94 machine language instructions of the 1802 microprocessor to a new set of about 30 more powerful and convenient instructions. Each type of statement in the new language is implemented by a machine code subroutine which carries out the desired operation. It differs from a basic interpreter in that most of the operations carried out by the subroutines are small ones, consisting of only a few machine code instructions, and the language is therefore a simple one without many of the features of basic. However quite powerful programs can be written with a few hundred CHIP-8 instructions.

This section introduces a version of CHIP-8 for the 1/4K Elf. Ten of the instructions are a subset of the full CHIP-8 set and are identical to those in CHIP-8. Two additional instructions, read a byte from the keyboard and display a byte on the hex display, have no exact counterparts in the CHIP-8 set.

CHIP-8 instructions consist of four hex digits. The first hex digit determines the type of instruction; there are therefore 16 basic kinds of CHIP-8 instructions. The next 3 hex digits are used in several different ways. They can be used to specify a memory location, and as there are 3 hex digits available, any memory location from 000 to FFF can be specified. In the demonstration interpreter only the two least significant hex digits are needed for this purpose because it is necessary to address only a single page of memory.

A basic feature of CHIP-8 is that it provides 16 one byte variables, designated VO through VF. Thus a single hex digit can be used to specify one of these variables. In many of the CHIP-8 instruc-

tions the second most significant hex digit is used for this purpose, leaving the last two hex digits available for other uses. In arithmetic operations the two variables to be added, etc. are specified by the second and third hex digit leaving the last hex digit to designate the type of arithmetic operation to carry out.

Before beginning a discussion of how the interpreter works, it is necessary to have an understanding of the language and its use. The instructions available are shown in Table 1.

*Table 1*  
**Demonstration Interpreter Instructions**

|      |   |
|------|---|
| 00MM | do a machine code subroutine at location MM (The machine code subroutine must end with D4)  |
| 10MM | go to MM; control is transferred to location MM in the interpretive code  |
| 20MM | do an interpreter subroutine at location MM (The interpreter subroutine must end with 009E)   |
| 4XKK | skip if $VX \neq KK$ ; the next interpreter instruction is skipped over if VX does not equal KK   |
| 6XKK | set $VX = KK$ ; variable X is made equal to KK  |
| 8XY0 | set $VX = VY$ ; variable X is made equal to variable Y  |
| 8XY1 | set $VX = VX \text{ or } VY$ ; variable X is made equal to the result of VX logically ored against VY (Note that VF is changed)   |
| 8XY2 | set $VX = VX \text{ and } VY$ ; variable X is made equal to the result of VX logically anded against VY (Note that VF is changed)   |
| 8XY4 | set $VX = VX + VY$ ; variable X is made equal to the sum of VX and VY (Note that VF becomes 00 if the sum is less than or equal to FF and 01 if the sum is greater than FF)   |
| 8XY5 | set $VX = VX - VY$ ; variable X is made equal to the difference between VX and VY (Note that VF becomes 00 if VX is less than VY and 01 if VX is greater than or equal to VY) |
| DXKK | display VX on the hex display, KK indicates the length of a pause for display   |
| FX00 | set VX equal to the switch byte; waits for the input button to be pushed and released   |

An easy way to see how these instructions are used is to illustrate them with a simple program. The interpreter is listed at the end of the chapter and can be used to run these sample programs.

To start let's look at the following program. It reads in 2 switch bytes, displays them, adds them, and displays the result. If overflow occurs, that is if the sum of the bytes is greater than FF, EE is also displayed. The program uses only 10 interpreter instructions. (The first instruction 3071 is actually machine code and transfers control on entry to the interpreter; it is not part of the interpretive code.) The interpreter has a program counter for interpretive code (R(5)) which is set on entry to the address of the first instruction (M(00 02)). The first interpretive language instruction is 63EE which sets variable number 3 equal to EE.

#### Interpretive Addition Program

| Addr. | Code | Notes  |
|-------|------|--|
| 00    | 3071 | entry to interpreter   |
| 02    | 63EE | set V3 equal to EE   |
| 04    | F400 | set V4 equal to switch byte, waits for in on, off  |
| 06    | D4FF | display V4 on hex display for about 1.8 seconds  |
| 08    | F500 | set V5 equal to switch byte  |
| 0A    | D5FF | display V5 on hex display  |
| 0C    | 8454 | set V4 equal to V4 + V5  |
| 0E    | D4FF | display V4, now the sum of V4 + V5   |
| 10    | 4F01 | skip next instruction if VF ≠ 01, remember VF will be set to 01 by the 8454 instruction if overflow occurs |
| 12    | D3FF | display V3 (V3 was set equal to EE) this instruction is skipped if VF is anything but 01                   |
| 14    | 1004 | go back to instruction 04 to wait for next number  |

The above program illustrates most of the demonstration interpreter instructions, an important exception is the interpreter subroutine call. Unlike the SEP register technique used in simple machine code programs, interpreter subroutines do not have to return to the main program but can be called from other subroutines. A stack is employed to store the return address when a subroutine call is made and successive calls to subroutines, with-

out returns, push the stack further down. In the demonstration interpreter the stack pointer, R(2), points to the last location used and is pushed down one before a new byte is added to the stack. Each time a return from a subroutine occurs the stack pointer is incremented by one.

The next program is a simple illustration of the use of an interpreter subroutine. A switch byte is entered and displayed. It is then counted down by three's until underflow occurs. A subroutine is used to implement the counting down by three.

#### Program to Illustrate Subroutine Use

| Addr. | Code | Notes   |
|-------|------|---|
| 00    | 3071 | entry to interpreter  |
| 02    | F500 | set V5 equal to switch byte, waits for in on, off   |
| 04    | D5FF | display V5 on hex display for about 1.8 seconds   |
| 06    | 200A | call interpreter subroutine at memory location 0A   |
| 08    | 1002 | on return from subroutine go to location 02 to read another switch byte                     |
| -     | -    | begin interpretive subroutine   |
| 0A    | 6603 | set V6 equal to 03  |
| 0C    | 8565 | set V5 equal to V5 - V6   |
| 0E    | D540 | display V5 for ca. 0.4 seconds  |
| 10    | 4F01 | skip next instruction if underflow occurs during the subtraction, VF equals 00 on underflow |
| 12    | 100C | transfer to location 0C to subtract three more  |
| 14    | 009E | return from subroutine  |

In the above program, the call to the subroutine uses one stack position to store the return address. When the interpreter is entered the stack pointer is set to location 71. On calling the subroutine it is decremented by one, to location 70, and 08, the location the interpreter should execute on return from the subroutine, is stored there. If we examine location 70 after running this program 08 will be found stored there. Two additional stack locations, 6E and 6F are used by the 8565 instruction, these locations become F5 and D3 respectively. An explanation of why this occurs is given in the demonstration interpreter listing.

The interpreter also includes an instruction, 00MM, which executes a machine code subroutine

at address MM. This is easily accomplished; the control section of the interpreter treats the machine code subroutine as if it were one of the subroutines written to execute a CHIP-8 instruction. All the subroutines which execute CHIP-8 instructions end with a D4 byte; this returns control to the calling section of the interpreter. As a result machine code subroutines must also end with a D4 byte.

The following program poses simple addition problems and illustrates most of the demonstration interpreter instructions. It contains a machine language subroutine which generates two random numbers when the in button is pushed. On entry, the program displays AA and the Q light comes on. When the input button is pressed a simple addition problem (base 10) is presented: for example 17 AD (for and) 32 E0 (for equals) may be displayed. If 00 is entered the problem is shown again, if the correct answer is entered it is displayed followed by AA. However if an incorrect answer is entered EE is shown followed by the correct answer. The program requires 36 interpreter instructions and a machine language subroutine of 25 bytes. An interpreter subroutine is used to convert a number from hex to decimal for display and a machine language subroutine is used to generate two random numbers in VD and VE. The displayed numbers are all less than 99 (base 10) to accommodate the hex display and the simple hex to decimal conversion routine which fails for numbers greater or equal to 100 (base 10).

#### Program for Addition Problems

| Add. | Code | Notes  |
|------|------|--|
| 00   | 3071 | entry to interpreter   |
| 02   | 60E0 | set V0 equal to E0   |
| 04   | 61EE | set V1 equal to EE   |
| 06   | 62AD | set V2 equal to AD   |
| 08   | 63AA | set V3 equal to AA   |
| 0A   | D300 | display V3 (AA) on the display but no delay for display  |
| 0C   | 004A | call machine language subroutine which generates random numbers in VD and VE when in is pushed |
| 0E   | 8BE0 | set VB equal to VE as preparation for summing the two random numbers                           |
| 10   | 8BD4 | set VB equal to VD + VE, sum of the two random numbers   |

|    |      |   |
|----|------|---|
| 12 | 203A | call the interpreter subroutine which converts from hex to decimal, answer is returned in VA and VB is changed  |
| 14 | 8CA0 | save answer on return from subroutine by setting VC equal to VA   |
| 16 | 8BE0 | set VB equal to VE, one of the random numbers   |
| 18 | 203A | call subroutine to make VA the decimal equivalent of VB   |
| 1A | DAFF | display VA, first random number (base 10)   |
| 1C | D2FF | display V2 (AD)   |
| 1E | 8BD0 | set VB equal to VE the other random number  |
| 20 | 203A | call subroutine to make VA the decimal equivalent of VB   |
| 22 | DAFF | display VA, second random number  |
| 24 | D0FF | display V0 (E0)   |
| 26 | F600 | make V6 the entered byte  |
| 28 | 4600 | skip the next instruction if V6 is equal to 00  |
| 2A | 1016 | here only if V6 is 00, back to 16 to repeat display   |
| 2C | D6FF | display V6, the entered byte  |
| 2E | 86C5 | set V6 equal to V6 - VC, VC is correct answer (base 10)   |
| 30 | 4600 | skip next instruction unless V6 equals 00, i.e. skip on wrong answer  |
| 32 | 100A | transfer to 0A to show AA if answer is correct  |
| 34 | D1FF | display V1 (EE)   |
| 36 | DCFF | display VC, correct answer  |
| 38 | 100C | transfer to 0C to begin next problem  |
| -  | -    | end of main, begin hex to decimal conversion subroutine, subroutine adds 06 to VB for every time 0A occurs, argument is passed in VB and returned in VA |
| 3A | 8AB0 | set VA equal to VB  |
| 3C | 6906 | set V9 equal to 06  |
| 3E | 680A | set V8 equal to 0A  |
| 40 | 8B85 | set VB equal to VB - V8, i.e. subtract 0A from VB   |

|    |          |   |
|----|----------|---|
| 42 | 4F00     | skip next instruction if VF equals 00, i.e. skip unless underflow   |
| 44 | 009E     | return from subroutine on underflow   |
| 46 | 8A94     | set VA equal to VA + V9, i.e. add 06 to VA  |
| 48 | 1040     | transfer to location 40 to subtract 0A from VB, this is the end of the subroutine   |
| —  | —        | start of machine language subroutine, random numbers from 1 through 50 (base 10) are generated in VD and VE, R(6) is used to point to VD and VE, see the interpreter listing for a better understanding of how this routine works |
| 4A | 7B       | entry point, turn Q on  |
| 4B | E6       | make R(6) the X register  |
| 4C | F8 FE A6 | load the address of VE to R(6)  |
| 4F | F8 33    | load 51 (base 10) to D  |
| 51 | FF 01    | subtract 01 from D  |
| 53 | 32 4F    | transfer to 4F if D is zero   |
| 55 | 3F 51    | transfer to 51 unless in pushed   |
| 57 | 73       | here when in pushed, store number in VE point R(6) to VD  |
| 58 | F8 32    | load 50 (base 10) to D  |
| 5A | FF 01    | subtract 01 from D  |
| 5C | 32 58    | transfer to 58 if D is zero   |
| 5E | 37 5A    | transfer to 5A unless in released   |
| 60 | 56       | store number in VD  |
| 61 | 7A D4    | turn Q off and return, end of program   |

The above program illustrates one of the weaknesses of CHIP-8. There is no way to pass arguments to interpreter subroutines except through the variables and we must execute a number of variable transfer instructions to use the hex to decimal interpreter subroutine. This weakness is partly overcome in the full interpreter by the inclusion of instructions which transfer the variables to and from memory. The full interpreter also includes an instruction which generates random numbers and a hex to decimal conversion routine. In the next section this program has been rewritten for the full interpreter.

Now let's look at the listing for the demonstration interpreter. It uses the 16 locations F0 through FF to store the 16 variables. The interpreter examines each instruction in turn and carries out the desired operation by calling the correct subroutine. It uses the following registers:

#### Demonstration Interpreter Register Use

- R(2) stack pointer
- R(3) set to address of machine code subroutine that carries out instruction, i.e. subroutine program counter
- R(4) program counter for control section of interpreter
- R(5) program counter for interpretive code
- R(6) VX pointer, points to one of 16 variables
- R(7) VY pointer, points to one of 16 variables
- R(C) used to point to a table of addresses

The interpreter is designed for use on a single page of memory and will work in the basic 1/4 K Elf as it stands. For expanded systems R(2), R(3), R(4), R(5), R(6), R(7), and R(C) have to have their high order bytes set to the page the interpreter resides on. Perhaps the simplest way to do this initialization for an expanded system is to change the entry point of the interpreter from 71 to 68 and add the following code from locations 68 through 73:

| Addr. | Code        | Notes   |
|-------|-------------|---|
| 68    | F8 00       | load page number to D, here 00 but interpreter can be on any page |
| 6A    | B2 B3 B4    | initialize registers  |
| 6D    | B5 B6 B7 BC | initialize registers  |
| 71    | F8 68 A2    | establish top of stack at M(68) instead of at M(71)               |

Note that the stack pointer is now initialized at location 68 instead of at location 71. Alternatively one can place the interpreter on a higher page in memory, do the initialization of the registers on page 00 and then transfer control to the interpreter. If this method is used the interpretive code can start at location 00 and R(5).0, the address of the first interpreter instruction, can be set to 00.

#### Demonstration Interpreter Listing

| Addr. | Code     | Notes                   |
|-------|----------|-------------------------|
| 71    | F8 71 A2 | establish stack pointer |

|    |             |  |    |             |  |
|----|-------------|--|----|-------------|--|
| 74 | F8 7A A4    | R(4) will be program counter for control section of interpreter  | —  | —           | and call subroutine, end of control section  |
| 77 | F8 02 A5    | R(5) is program counter for interpretive code, first instruction is at M(02)                                       | 9B | 45 56       | begin subroutine for 6XKK instruction  |
| 7A | D4          | establish program counter for control section  | 9D | D4          | load KK to D, store in VX  |
| 7B | E2          | make R(2) the X register, this is the entry point for return to control section after completing a subroutine call | —  | —           | return to control section  |
| 7C | 45 AF       | load first half of instruction and save it in R(F).0   | 9E | 42          | 9E through A0 is a machine code subroutine that restores R(5) on return from interpreter subroutine                            |
| 7E | F6 F6 F6 F6 | shift right to get most significant digit—most significant digit determines type of instruction                    | 9F | A5 D4       | load return address from stack   |
| 82 | 32 98       | if D is zero (type 0 instruction) we have machine code subroutine call, transfer to location 98                    | —  | —           | restore R(5) and return  |
| 84 | F9 A0       | else or against A0 to get address from table of subroutine locations (see locations A1 to AF)                      | —  | —           | the next 15 bytes are the subroutine locations   |
| 86 | AC          | save address in R(C).0   | A1 | B5 B0 E5 B8 | i.e. go to B5 for 10MM instructions, go to B0 for 20MM instructions, etc. illegal instructions go to E5 where they are ignored |
| 87 | 8F          | bring back instruction   | A5 | E5 9B E5 C0 | subroutine for 20MM instructions   |
| 88 | F9 F0       | or against F0 to get VX address  | A9 | E5 E5 E5 E5 | load return address to D   |
| 8A | A6          | establish R(6) as VX pointer   | AD | E7 E5 DD    | save on stack, push stack down first   |
| 8B | 05          | load second half of instruction, note that R(5) is left pointing to second half of instruction                     | B0 | 15 85       | restore R(5) so that it points to MM   |
| 8C | F6 F6 F6 F6 | shift right to get VY pointer  | B2 | 22 52       | rest of this subroutine is shared with 10MM instructions   |
| 90 | F9 F0       | or against F0 to get VY address  | B4 | 25          | load MM change R(5) to point to new address  |
| 92 | A7          | establish R(7) as VY pointer   | B5 | 45 A5       | return   |
| 93 | 0C A3       | pick up subroutine address from table and point R(3) to subroutine   | B7 | D4          | begin subroutine for 4XKK instruction  |
| 95 | D3          | call subroutine to do instruction  | —  | —           | load KK to D   |
| 96 | 30 7B       | on return from subroutine go to 7B for next instruction  | B8 | 45          | make R(6) the X register, the VX pointer   |
| 98 | 45 30 94    | here for machine code subroutine, load address to D and go to 94 to establish R(3)                                 | B9 | E6          | x'or VX against KK   |
|    |             |  | BA | F3          | return immediately if D equals 0, i.e. if VX equals KK   |
|    |             |  | BB | 32 BF       | else increment instruction program counter twice   |
|    |             |  | BD | 15 15       | return   |
|    |             |  | BF | D4          | here begin the 8XYN instructions   |
|    |             |  | —  | —           | load advance YN to D   |
|    |             |  | C0 | 45          | and off N to get ON in D   |
|    |             |  | C1 | FA 0F       | go to C8 unless N is zero  |
|    |             |  | C3 | 3A C8       |  |

## The CHIP-8 Language

|       |          |   |
|-------|----------|---|
| C5    | 07 56    | load VY, write to VX  |
| C7    | D4       | return  |
| —     | —        | here on other 8XYN instructions, makes up FN D3 on stack, transfers control to stack and obeys the two instructions, uses R(2) as program counter |
| C8    | AF       | save 0N   |
| C9    | 22       | push stack down   |
| CA    | F8 D3 73 | load D3 to D, write to stack  |
| CD    | 8F F9 F0 | load 0N, or against F0 to get F1, F2, F4, or F5   |
| D0    | 52       | write to stack  |
| D1    | E6       | make VX pointer the X register  |
| D2    | 07       | load VY to D  |
| D3    | D2       | go to stack to obey FN D3 instructions  |
| D4    | 56       | on return save result as VX   |
| D5    | F8 FF A6 | point R(6) to VF  |
| D8    | F8 00    | clear D   |
| DA    | 7E 56    | shift DF into D and save as VF  |
| DC    | D4       | return  |
| —     | —        | begin FX00 subroutine   |
| DD    | 7B       | Q on to indicate waiting for byte   |
| DE    | 3F DE    | wait for in on  |
| E0    | 37 E0    | wait for in off   |
| E2    | E6       | make VX pointer the X register  |
| E3    | 6C       | switch byte to VX   |
| E4    | 7A       | turn Q off  |
| E5    | 45 D4    | advance instruction counter, return—also used for illegal instructions  |
| —     | —        | begin DXKK subroutine   |
| E7    | E6       | make VX pointer the X register  |
| E8    | 64       | display VX  |
| E9    | 45 BF    | load KK to R(F).1   |
| EB    | 2F 9F    | decrement R(F), load R(F).1   |
| ED    | 3A EB    | go to EB unless D is zero, delay loop   |
| EF    | D4       | return—end of interpreter   |
| F0-FF | —        | locations where the 16 interpreter variables are stored   |

This section contains a brief discussion of the CHIP-8 language and a list of the available instructions. Further information about RCA's VIP machine and about CHIP-8 can be found in two articles by Joseph Weisbecker ("COSMAC VIP, the RCA Fun Machine", in the August, 1977 Byte magazine p. 30, and "An Easy Programming System", in the December, 1978 Byte magazine p. 108) and in RCA's literature. The full CHIP-8 instruction set is listed in the table at the end of this chapter.

Many of the basic features of the CHIP-8 language are explained and illustrated in section 2 and the demonstration interpreter contains ten instructions which are identical to those in the full CHIP-8 set. The complete language is designed for use with low resolution graphics and the display subroutine is the longest and most complex of the subroutines in the interpreter. A number of TV games have been written with CHIP-8 and it is well suited for this purpose. The display instruction is used in conjunction with a memory pointer and the CHIP-8 variables and has the form DXYN. The values of VX and VY indicate where on the video display to show information, and the value of N indicates how many bytes to display. A memory pointer, called I, gives the starting address of the information to be displayed and must be set by other instructions. Positions in the display field are determined by a rectangular coordinate system with the origin in the upper left corner; 64 horizontal positions, designated by VX and 32 vertical positions designated by VY, are available. The bytes to be displayed are exclusively ored against the display field; an important feature for TV games. Portions of memory bytes which extend beyond the display field on the right or at the bottom are truncated, there is no wrap around.

Another important feature of the language is the 16 one byte variables, V0 through VF, which are held in random access memory. Two of these variables V0 and VF are used for special purposes. V0 is used in a kind of computed go to statement, the BMMM instruction. Control is transferred to location MMM to which has been added the value of V0. As in the demonstration interpreter, VF is used to indicate overflow in arithmetic operations. It is also used to indicate when a display instruction attempts to show a position which is already being displayed. As the display instruction exclusively or's the data to be displayed against the display field, such an attempt turns off the displayed position. VF is set to 01 to indicate this occur-

rence. This serves as a simple way to determine if a missile has struck a target in a TV game.

A third important feature of CHIP-8, already mentioned in the discussion of the display routine, is the memory pointer, I. The memory pointer can be set both directly and indirectly; besides its use as a display pointer, it also serves as a pointer for transferring variables to and from memory.

The full CHIP-8 instruction set has six skip instructions all of which follow the principle of the skip instruction included in the demonstration interpreter. That is, the next interpreter instruction is skipped over if on testing a condition it is found to be true.

The instructions which have 8 as the first hexadecimal digit perform arithmetic and logic operations and are all included in the demonstration interpreter. Note again that VF is used to indicate overflow and that the value of VF is changed by 8XY1, 8XY2, 8XY4, and 8XY5 instructions.

A number of instructions which were not included in the demonstration interpreter are the "F" instructions. Several of these are used in conjunction with the memory pointer. For example the FX29 instruction points I at a 5 byte memory pattern which corresponds to the least significant hex digit of VX. If V7 were 38 and a F729 instruction were executed I would point to the first byte of the series F0, 90, F0, 90, F0 (a pattern for the symbol "8") and a DXY5 instruction would show an "8" on the display. The FX33 instruction is a binary to decimal conversion routine. The value of VX is converted to a 3 digit decimal number with the hundreds digit stored at location I, the tens digit at location I + 1, and the units digit at location I + 2. The FX55 and FX65 instructions use the memory pointer to transfer variables to memory and to transfer values from memory to the variables, respectively.

Other "F" instructions include a settable tone generator (FX18) (see the section on Hardware Differences), an instruction to set a timer (FX15), an instruction to read the timer (FX07), and an instruction to read the keyboard (FX0A). An additional "F" instruction has been added for the Elf; FX75, which displays the value of VX on the hex display.

Other useful instructions which were not present in the demonstration interpreter include a random number generator (CXKK where KK is anded against a random byte before being transferred to VX), and an instruction which adds a byte to one of the variables, 7XKK. Two of the CHIP-8 in-

structions 00E0 (erase the display) and 00EE (return from a CHIP-8 subroutine) are implemented as machine code subroutines resident in the interpreter itself. They are therefore dependent upon the page where CHIP-8 is located and will have to be changed if CHIP-8 is relocated. This also is the reason that the return from a subroutine is 009E in the demonstration interpreter and 00EE in the full CHIP-8 interpreter.

To illustrate the use of the full instruction set, let's rewrite one of the programs that used the demonstration interpreter, the one involving addition problems. The following program constructs simple addition problems using two randomly chosen numbers between 0 and 127. On entry to the program a problem is presented, e.g.  $076 + 093 = ?$ . An answer is entered through the keyboard one digit at a time (i.e. 1, 6, 3) and when the last digit is entered 163 is displayed. A C follows the entered number if it is correct and an E if it is incorrect. In the case of an incorrect answer the correct answer is also shown. Another problem is given when any key is entered. The program consists of 67 CHIP-8 instructions and also uses 32 bytes for constants and work space.

#### Program for Addition Problems

| Addr. | Code | Notes  |
|-------|------|--|
| 0200  | 00E0 | erase display  |
| -     | -    | first set up problems and answer                                   |
| 0202  | CD7F | VD equals random number  |
| 0204  | CE7F | VE equals random number  |
| 0206  | 8CD0 | VC = VD  |
| 0208  | 8CE4 | VC = VD + VE (the answer)  |
| -     | -    | next convert to decimal and display the problem                    |
| 020A  | A2A2 | point I to work space  |
| 020C  | 6A00 | set VA = 00, display pointer                                       |
| 020E  | 6B00 | set VB = 00, display pointer                                       |
| 0210  | FD33 | M(I) equals 3 digit decimal equivalent of VD                       |
| 0212  | F265 | V0, V1, V2 equals M(I)   |
| 0214  | 2276 | call CHIP-8 subroutine (displays 3 digit number in V0, V1, and V2) |
| 0216  | A288 | point I to + pattern   |
| 0218  | 7A07 | VA = VA + 07, display pointer                                      |
| 021A  | DAB5 | display + pattern  |
| 021C  | A2A2 | point I to work space  |

|      |      |  |      |       |   |
|------|------|--|------|-------|---|
| 021E | 7A08 | VA = VA + 08, display pointer                          | 0264 | 6B10  | set VB = 10, display pointer                            |
| 0220 | FE33 | M(I) equals 3 digit decimal equivalent of VE           | 0266 | 2276  | call subroutine to display correct answer               |
| 0222 | F265 | V0, V1, V2 equals M(I)                                 | 0268 | 660E  | V6 = 0E   |
| 0224 | 2276 | call subroutine to display VE                          | 026A | 6A26  | VA = 26, display pointer                                |
| 0226 | A28E | point I to = pattern                                   | 026C | 6B08  | VB = 08, display pointer                                |
| 0228 | 7A07 | VA = VA + 07, display pointer                          | 026E | F629  | point I to C or E pattern                               |
| 022A | DAB4 | display = pattern                                      | 0270 | DAB5  | display C or E  |
| 022C | A292 | point I to ? pattern                                   | 0272 | F00A  | wait for any input                                      |
| 022E | 6A18 | set VA = 18, display pointer                           | 0274 | 1200  | to 0200 for next problem                                |
| 0230 | 6B08 | set VB = 08, display pointer                           | —    | —     | subroutine to display 3 digit number held in V0, V1, V2 |
| 0232 | DABF | display ? pattern                                      | 0276 | F029  | point I to pattern for V0                               |
| —    | —    | now read in possible answer, display it                | 0278 | DAB5  | display it  |
| 0234 | F00A | V0 = least significant digit of switch byte            | 027A | 7A05  | VA = VA + 05, display pointer                           |
| 0236 | F10A | V1 = switch byte (LSD)                                 | 027C | F129  | point I to pattern for V1                               |
| 0238 | F20A | V2 = switch byte (LSD)                                 | 027E | DAB5  | display it  |
| 023A | DABF | display ? pattern (erases it)                          | 0280 | 7A05  | VA = VA + 05, display pointer                           |
| 023C | 6A15 | set VA = 15, display pointer                           | 0282 | F229  | point I to pattern for V2                               |
| 023E | 2276 | call subroutine to display entered answer              | 0284 | DAB5  | display it  |
| —    | —    | now compare answers, right to 025C, wrong to 0262      | 0286 | 00EE  | return from subroutine                                  |
| 0240 | A2A5 | point I to work space                                  | —    | —     | patterns and work space                                 |
| 0242 | F255 | V0, V1, V2 to memory                                   | 0288 | 2020  | pattern for + sign                                      |
| 0244 | A2A2 | point I to work space                                  | 028A | F820  |   |
| 0246 | FC33 | M(I) equals 3 digit decimal equivalent of answer       | 028C | 2000  |   |
| 0248 | F565 | V0, V1, V2—correct answer<br>V3, V4, V5—entered answer | 028E | 00F0  | pattern for = sign                                      |
| 024A | 8305 | V3 = V3 - V0   | 0290 | 00F0  |   |
| 024C | 3300 | skip if V3 = 00  | 0292 | FFFF  | pattern for ? sign                                      |
| 024E | 1262 | go to 0262, error                                      | 0294 | 0303  |   |
| 0250 | 8415 | V4 = V4 - V1   | 0296 | 03FF  |   |
| 0252 | 3400 | skip if V4 = 00  | 0298 | FFC0  |   |
| 0254 | 1262 | go to 0262, error                                      | 029A | C0C0  |   |
| 0256 | 8525 | V5 = V5 - V2   | 029C | C0C0  |   |

| 0262 | 6A15 | set VA = 15, display pointer                           |      |       |   |

*Table 2*

**Full Interpreter Instructions**

|      |  |
|------|--|
| 0MMM | do a machine code subroutine at location 0MMM (The machine code subroutine must end with D4) |
| 1MMM | go to 0MMM; control is transferred to location 0MMM in the interpretive code                 |
| 2MMM | do an interpreter subroutine at location   |

|      |   |      |   |
|------|---|------|---|
|      | OMMM (the interpreter subroutine must end with 00EE)  |      | equals the least significant digit of the keyboard  |
| 3XKK | skip if VX = KK; the next interpreter instruction is skipped over if VX equals KK   | EXA1 | skip if VX ≠ hex key; skip next instruction if the least significant digit of VX does not equal the least significant digit of the keyboard |
| 4XKK | skip if VX ≠ KK; the next interpreter instruction is skipped over if VX does not equal KK   | FX07 | set VX to the value of the timer; timer is counted down in interrupt routine  |
| 5XY0 | skip if VX = VY; the next interpreter instruction is skipped over if VX equals VY (see 9XY0)  | FX0A | set VX = hex key; sets VX equal to the least significant digit of the keyboard, waits for in on, off  |
| 6XKK | set VX = KK; variable X is made equal to KK   | FX15 | set timer to VX; timer is counted down in interrupt routine so 01 is ca. 1/60 th second   |
| 7XKK | set VX = VX + KK; add KK to variable X  | FX18 | set tone duration to VX; turns Q on for duration specified by VX, 01 is ca. 1/60 th second  |
| 8XY0 | set VX = VY; variable X is made equal to variable Y   | FX1E | set I to I + VX; add the value of VX to the memory pointer  |
| 8XY1 | set VX = VX or VY; variable X is made equal to the result of VX logically ored against VY (Note that VF is changed)   | FX29 | point I to pattern for least significant digit of VX  |
| 8XY2 | set VX = VX and VY; variable X is made equal to the result of VX logically anded against VY (Note that VF is changed)   | FX33 | convert VX to decimal; 3 decimal digits are stored at M(I), M(I + 1), and M(I + 2), I does not change                                       |
| 8XY4 | set VX = VX + VY; variable X is made equal to the sum of VX and VY (Note that VF becomes 00 if the sum is less than or equal to FF and 01 if the sum is greater than FF)  | FX55 | save V0 through VX in memory at locations specified by I, V0 at M(I), V1 at M(I + 1), etc., I becomes I + X + 1                             |
| 8XY5 | set VX = VX - VY; variable X is made equal to the difference between VX and VY (Note that VF becomes 00 if VX is less than VY and 01 if VX is greater than or equal to VY)  | FX65 | transfer memory locations specified by I to variables V0 through VX, V0 becomes M(I), V1 becomes M(I + 1), etc. I becomes I + X + 1         |
| 9XY0 | skip if VX ≠ VY; the next interpreter instruction is skipped over if VX does not equal VY (see 5XY0)  | FX75 | display the value of VX on the hex display  |
| AMMM | point I at OMMM; the memory pointer is set to OMMM  | 00E0 | erase the display (actually a machine language subroutine resident in the interpreter)  |
| BMMM | go to OMMM + V0, the value of V0 is added to OMMM and control is transferred to the resulting location  |      |   |
| CXKK | set VX to a random byte; random byte is anded against KK first  |      |   |
| DXYN | display N byte pattern at coordinates VX, VY; I (memory pointer) gives starting address of locations to be displayed. The displayed locations are exclusively ored against display field. VF becomes 01 if some of the display field is already set, 00 if it is not. |      |   |
| EX9E | skip if VX = hex key; skip next instruction if the least significant digit of VX  |      |   |

### Hardware Differences between 1802 Computers

The most important difference between the various versions of the COSMAC ELF and the COSMAC VIP is the keyboard. The COSMAC VIP has a hex keyboard; however it is not connected to an input port. Instead the least significant 4 bits of a bus output byte (Out 2, 62) are decoded and the 16 output lines connected to the corresponding hex keys. Each key is connected to one of the flag lines (EF3). To determine which key is depressed requires a software routine which scans the keyboard. Scanning is done by repeatedly outputting the 16 possible least significant hex digits and examining the flag line to see which digits cause it

to be pulled low. Debouncing is also carried out within the software routines; there is an approximately 1/15 second software delay to debounce both the opening and closing of a keyboard switch.

COSMAC ELF computers on the other hand are variable in design and have a variety of ways to input information from keyboards or switches. Indeed the September, 1976 issue of Popular Electronics describes a way to connect a scanned hex keyboard, much like that contained in the VIP, to the ELF. However most of the commercially available ELFs (e.g. Super Elf and Elf-2) have latched hex keyboards with roll-over. The latches are connected to an input port and one can examine the contents of these latches at any time under software control. A hardware debounced button is connected to one of the external flags (EF4). This button (the in button) can be used as a device to indicate to a software routine that we wish the switch latches read. An additional feature of the Elf is the ability to carry out direct memory access input from the keyboard by depressing the in button when the computer is in the load mode. This feature is not required by the VIP which has an operating system in ROM.

These different methods in inputting information from the keyboard have different advantages and disadvantages, neither is really totally satisfactory. The VIP's keyboard has one significant advantage. All of the keys are connected directly to a flag line and it is possible to tell, with software, when a key is being depressed and if so which one. A quick response to keyboard entry is therefore possible and this property is particularly desirable for TV games. It also makes possible an operating system which enters bytes directly from the keyboard to memory without the necessity of pushing an in button. These features are more difficult with a roll-over latched keyboard like that found in many ELFs. Entered bytes can only be read from the latches and there is no way, with software, to determine when a single key is repeatedly entered; that is we could never determine if B, B, B, B was entered because the contents of the latches would never change. This difficulty could, of course, be overcome with some simple hardware changes to the ELF.

The advantage of the ELF keyboard is that the contents of the keyboard latches can be transferred directly to memory by instituting a direct memory access cycle. This, in fact, is what makes the ELF a viable machine without read only memory. However the ELF would be easier to use if the contents

of the keyboard latches were displayed and if a signal were provided which made it unnecessary to push the in button.

Another hardware difference is in the treatment of the Q line. In the VIP the Q line is attached to a simple oscillator, and this in turn can be connected to a speaker. Hence in the VIP when the Q line is turned on, a tone is heard in the loudspeaker. This feature can be added to an Elf without much difficulty. It should perhaps be mentioned that the VIP has room on board for one input and one output port, the output port uses out-3 (63), and the input port uses in-3 (6B).

Rather than attempt to change the ELF to a VIP by making hardware changes, this booklet accepts the ELF's as they are and makes the software changes in CHIP-8 to accommodate ELF's. Unfortunately ELF's are not built to a standard design like the VIP and it is therefore difficult to write software which will suit all ELF users. To compensate for this a detailed listing of the interpreter is presented in the next section. It is hoped that sufficient information is given so that those with ELF's which differ from those commercially available will be able to modify the interpreter to suit their machines.

### A Complete Elf CHIP-8 Interpreter

This section provides a listing and a discussion of a version of CHIP-8 for COSMAC ELF's. The main listing of the interpreter is designed for a 4K Elf with memory pages 00 through 0F, the configuration most commonly used by the commercially available ELF's. It is also possible to use CHIP-8 in the 1 1/4 K ELF's described in the articles in Popular Electronics, but to do so is very tedious unless the switches are replaced with a latched decoded keyboard. This machine has memory pages 00, 04, 05, 06, and 07 and a version of CHIP-8 for such a machine will also be described. The necessary changes to CHIP-8 will be discussed in the notes included with the full interpreter listing. Similar changes are required when CHIP-8 is relocated in memory and this example may aid those with other styles of machines.

The first consideration in modifying CHIP-8 for use on the ELF is page use. The following page use was chosen for the 4K Elf's with memory pages 00 through 0F:

| Page | Use                        |
|------|----------------------------|
| 00   | first half of interpreter  |
| 01   | second half of interpreter |

|                  |                                       |
|------------------|---------------------------------------|
| 02 - 0D          | reserved for interpretive code        |
| 0E (first half)  | character table and interrupt routine |
| 0E (second half) | variables, work space and stack       |
| 0F               | display page                          |

This choice of page usage maximizes the similarity of ELF CHIP-8 and VIP CHIP-8. However it is possible to relocate the code to other places in memory and it might be better to accept the changes in CHIP-8 and place the interpreter on pages 0C and 0D. Relocation is necessary to implement the 1 1/4 K version. Because of this, some changes in the language are necessary for the 1 1/4 K version and the instruction 00E0 becomes 04E0 and 00EE becomes 04EE. Page use for the 1 1/4 K version is as follows:

| Page             | Use  |
|------------------|--|
| 00               | display page   |
| 04               | first half of interpreter  |
| 05               | second half of interpreter   |
| 06 (first half)  | character table and interrupt routine  |
| 06 (second half) | variables, work space and stack (There is room for a small operating system in the middle of page 6) |
| 07               | interpretive code  |

Register use is the same as it is in the VIP version of CHIP-8 as follows:

| Use of Registers |  |
|------------------|--|
| High             | Low  |
| R(0)             | DMA address  |
| R(1)             | interrupt address                                  |
| R(2)             | stack, sometimes X register                        |
| R(3)             | program counter for interpreter subroutines        |
| R(4)             | program counter for control section of interpreter |
| R(5)             | CHIP-8 instruction program counter                 |
| R(6)             | variable pointer, the VX pointer                   |
| R(7)             | variable pointer, the VY pointer                   |
| R(8)             | timer  |
| R(9)             | random numbers                                     |

|      |   |
|------|---|
| R(A) | the I pointer   |
| R(B) | display page pointer  |
| R(C) | used for scratch but available for machine code subroutines |
| R(D) | used for scratch but available for machine code subroutines |
| R(E) | used for scratch but available for machine code subroutines |
| R(F) | used for scratch but available for machine code subroutines |

### Complete CHIP-8 Interpreter Listing

| Add. | Code     | Notes  |
|------|----------|--|
| —    | —        | first initialize the registers   |
| 0000 | F8 0E B1 | high order interrupt address<br>replace 00E with 06 for 1 1/4K Elf                                 |
| 03   | F8 46 A1 | low order interrupt address  |
| 06   | F8 0F BB | establish display page, replace 0F with 00 for 1 1/4K Elf  |
| 09   | F8 0E B2 | establish high order stack address<br>replace 0E with 06 for 1 1/4K Elf                            |
| 0C   | B6       | establish page for variables, work space (same as stack page)                                      |
| 0D   | F8 CF A2 | establish low order stack address  |
| 10   | F8 01 B5 | high order address for first CHIP-8 instruction, replace 01 with 05 for 1 1/4K Elf                 |
| 13   | F8 FC A5 | low order address for first CHIP-8 instruction, replace FC with FA for 1 1/4K Elf                  |
| 16   | F8 00 B4 | establish control section program counter, replace 00 with 04 for a 1/4K Elf                       |
| 19   | F8 1C A4 | establish low order address for control section program counter                                    |
| 1C   | D4       | make R(4) the program counter, this ends initialization of registers                               |
| —    | —        | begin control section of interpreter, on return from interpreter subroutine location 1D is entered |
| 1D   | 96 B7    | establish high order VY pointer  |

|    |             |  |    |             |  |
|----|-------------|--|----|-------------|--|
| 1F | E2          | establish x-register   | 46 | 45          | load advance—2nd byte of interpreter instruction   |
| 20 | 94 BC       | make R(C).1 the current page   |    |             |  |
| 22 | 45          | load first byte of a CHIP-8 instruction to D   | 47 | 30 40       | go to location 40 to set R(3).0 and call subroutine  |
| 23 | AF          | save 1st byte of instruction in R(F).0   | —  | —           | end of control section, except see tables of addresses   |
| 24 | F6 F6 F6 F6 | shift right 4 times to get most significant digit  | 49 | 22 69 12 D4 | these 4 bytes are a machine code subroutine to turn on 1861 (TV)—obeyed in usual way as a machine code subroutine  |
| 28 | 32 44       | go to 44 if most significant digit is 0, we have a machine language subroutine                       |    |             |  |
| 2A | F9 50       | else or immediate against 50 to make pointer to table of subroutine locations                        | 4D | 00 00 00 00 | unused   |
| 2C | AC          | save result in R(C).0, the register used as a pointer  | —  | —           | next 15 bytes are high order addresses for interpreter subroutines, notes show most significant digit of instruction (Note add 04 to each address for 1 1/4K Elf)  |
| 2D | 8F          | bring back 1st byte of instruction   |    |             |  |
| 2E | F9 F0       | or immediate against F0 to make VX pointer   | 51 | 01 01 01 01 | 1 2 3 4  |
| 30 | A6          | save in R(6).0, the VX pointer   | 55 | 01 00 01 01 | 5 6 7 8  |
| 31 | 05          | load 2nd byte of instruction   | 59 | 01 01 01 01 | 9 A B C  |
| 32 | F6 F6 F6 F6 | shift right to get most significant digit  | 5D | 00 01 01    | D E F  |
| 36 | F9 F0       | or immediate against F0 to make VY pointer   | 60 | 00          | unused   |
| 38 | A7          | save in R(7).0, the VY pointer   | —  | —           | low order address—same for 1 1/4K Elf  |
| 39 | 4C B3       | interpreter high order subroutine address from table to R(3).1                                       | 61 | 7F 78 86 8E | 1 2 3 4  |
| 3B | 8C FC 0F AC | set up pointer to table of low order subroutine addresses  | 65 | 98 FC 00 C2 | 5 6 7 8  |
| 3F | 0C A3       | low order subroutine address from table to R(3).0, R(3) now points to correct interpreter subroutine | 69 | 94 F1 B2 DF | 9 A B C  |
| 41 | D3          | change to subroutine program counter   | 6D | 70 9C 05    | D E F  |
| 42 | 30 1D       | subroutines end with D4, return here and go back to treat another interpreter instruction            | —  | —           | Now starts the remainder of the interpreter subroutines  |
| —  | —           | comes to location 44 for machine code subroutines  | —  | —           | entry to the display subroutine instruction, DXYN, review material in section 3 to see what it does. R(6) is used to point to work space, R(A) is I (the memory pointer), R(7).0 and R(D).0 are used to store N the number of bytes to display, and R(C) is used as pointer in to display page |
| 44 | 8F          | reload 1st byte of CHIP-8 instruction  | 70 | 06 BE       | load VX, save in R(E).1  |
| 45 | B3          | save in R(3).1, high order machine code subroutine address   | 72 | FA 3F       | and against 3F (only 64 positions across display field)  |
|    |             |  | 74 | F6 F6 F6    | shift right 3 times (gets row address, i.e. 0-7 in display page)   |
|    |             |  | 77 | 22 52       | save word address on stack   |
|    |             |  | 79 | 07          | load VY  |

|    |          |   |    |          |   |
|----|----------|---|----|----------|---|
| 7A | FE FE FE | shift left 3 times to make space for row address  | A4 | 16 8F 56 | save 2nd word in work   |
| 7D | F1       | or on row address, now have address of word some part of which VX, VY point to  | A7 | 16       | point R(6) to next work space   |
| 7E | AC       | save in R(C).0  | A8 | 30 89    | repeat till all display words treated   |
| 7F | 9B BC    | complete address by setting R(C).1 to display page address  | AA | 00       | idles here after housekeeping, see locations F3 through FB, still have to transfer work to display—R(C) points to first word to change in display field |
| 81 | 45       | load advance, 2nd half of instruction   | AB | EC       | make R(C) the X register  |
| 82 | FA 0F    | and off number of bytes to display  | AC | F8 D0    | load starting address of work   |
| 84 | AD A7    | save in R(D).0 and R(7).0   | AE | A6       | R(6) points to work   |
| 86 | F8 D0    | load starting address of work space   | AF | F8 00 A7 | 00 to R(7).0 and eventually to VF   |
| 88 | A6       | R(6) now points to work space   | B2 | 8D       | load number bytes to display, reenters here until done  |
| 89 | F8 00 AF | establish R(F).0 as a source of 00  | B3 | 32 D8    | all done?, to D8 to set VF and exit   |
| 8C | 87       | load number of bytes to display (a reentry point)   | B5 | 06       | load byte from work   |
| 8D | 32 F3    | to location F3 for housekeeping if all done or if no bytes to display   | B6 | F2       | and against display field   |
| 8F | 27       | decrement number of bytes to display  | B7 | 2D       | decrement bytes to display  |
| 90 | 4A BD    | load advance, load display byte and save in R(D).1  | B8 | 32 BD    | to BD if result of and is 00, i.e. no points already set  |
| 92 | 9E       | reload VX   | BA | F8 01 A7 | if points set make R(7).0 and eventually VF, 01   |
| 93 | FA 07 AE | and against 07, save in R(E).0, this is position in word—say R(A) pointed to a location containing FF (1111 1111) and least significant 3 bits of VX were (011)—routine from here to A9 would make two adjacent work locations (0001 1111) and (1110 0000), i.e. it would shift the word to be displayed over by 3 bits and fill in to left and right with 0. | BD | 46       | reload work to D (load advance)   |
| 96 | 8E       | load word position  | BE | F3       | x'or against display field  |
| 97 | 32 A2    | to A2 if 00, no shift needed  | BF | 5C       | write result to display field   |
| 99 | 9D F6 BD | shift 1 bit to DF, 0 to MSB of D  | C0 | 02       | reload VX   |
| 9C | 8F 76 AF | transfer DF to R(F).0, DF to MSB, LSB to DF   | C1 | FB 07    | are we at the end of a row?   |
| 9F | 2E 30 96 | repeat number of times in word address  | C3 | 32 D1    | if we are quit, no wrap around else increment R(C)  |
| A2 | 9D 56    | save 1st word in work   | C5 | 1C       | load next word from work  |
|    |          |   | C6 | 06       | repeat test for already set bits  |
|    |          |   | C7 | F2 32 CD | 01 to R(7).0 if bits set  |
|    |          |   | CA | F8 01 A7 | load from work again  |
|    |          |   | CD | 06       | x'or against field and write to field   |
|    |          |   | CE | F3 5C    | decrement R(C), increment R(6)  |
|    |          |   | D0 | 2C 16    | load R(C).0 add 08  |
|    |          |   | D2 | 8C FC 08 | load new address to R(C).0  |
|    |          |   | D3 | AC       | if DF is 0 go to B2 to do more, else we've run over bottom and should return  |
|    |          |   | D6 | 3B B2    | comes here when all done  |
|    |          |   | —  | —        |   |

|    |          |   |      |             |   |
|----|----------|---|------|-------------|---|
| D8 | F8 FF A6 | load VF address to R(6).0   | 0100 | 45          | load KK to D  |
| DB | 87 56    | load R(7).0 (either 00 or 01) and store in VF   | 01   | E6          | make R(6), VX, the X register   |
| DD | 12 D4    | fix up stack and return to control section  | 02   | F4          | add KK to VX  |
| DF | 00       | unused—done with main part of display routine see F3—FB, a patch for housekeeping                             | 03   | 56          | write result to VX  |
| —  | —        | entry point for 00E0 instruction (04E0 for 1 1/4K Elf) a machine code subroutine that erases the display page | 04   | D4          | return to control section   |
| E0 | 9B BF    | load display page address to R(F).1   | —    | —           | all F instructions enter here and are sent to correct subroutines by changing R(3)  |
| E2 | F8 FF AF | load FF to R(F).0   | 05   | 45          | load advance—2nd byte of F instruction is location to transfer to on this page  |
| E5 | F8 00    | load 00 to D  | 06   | A3          | change R(3) subroutine program counter to correct address   |
| E7 | 5F       | store via F   | —    | —           | entry for FX07 subroutine   |
| E8 | 8F 32 DE | load R(F).0, return from subroutine if D is 00, all done  | 07   | 98          | load timer value to D (see interrupt routine)   |
| EB | 2F 30 E5 | else decrement R(F) and go back to blank another memory location  | 08   | 56 D4       | write to VX and return  |
| —  | —        | entry point for 00EE instruction (04EE for 1 1/4K Elf) retrieves interpretive code address from stack         | —    | —           | entry for FX0A subroutine   |
| EE | 42 B5    | retrieve high order address   | 0A   | 3F 0A 37 0C | wait for in on, off   |
| F0 | 42 A5    | then low order address R(5) now set   | 0E   | 22          | push down stack   |
| F2 | D4       | return to control section   | 0F   | 6C          | read switch byte  |
| —  | —        | part of display routine, resets memory pointer  | 10   | FA 0F       | and against 0F to get least significant digit (This corresponds to original Chip-8, could and against FF to read complete byte) |
| F3 | 8D A7    | load number bytes to display, save in R(7).0  | 12   | 12 56       | restore stack, write to VX  |
| F5 | 87       | load R(7).0 to D  | 14   | D4          | return to control section   |
| F6 | 32 AA    | if 00 done, go to AA to wait for DMA  | —    | —           | entry for FX15 subroutine   |
| F8 | 2A 27    | decrement R(A) (memory pointer) and R(7)  | 15   | 06          | load VX to D  |
| FA | 30 F5    | go back to check if done  | 16   | B8 D4       | save in R(8).1 and return   |
| —  | —        | entry for 6XKK subroutine   | —    | —           | entry for FX18 subroutine   |
| FC | 45       | load KK to D  | 18   | 06          | load VX to D  |
| FD | 56 D4    | write to VX and return  | 19   | A8 D4       | save in R(8).0 and return (see interrupt routine for FX15 and FX18 explanation)   |
| FF | 00       | unused, end of page 00 (04 for 1 1/4K Elf)  | —    | —           | the next 3 bytes are used by the FX33 subroutine  |
| —  | —        | begin page 01 (05 for 1 1/4K Elf)   | 1B   | 64          | 100 (base 10)   |
| —  | —        | entry for 7XKK subroutine   | 1C   | 0A          | 10 (base 10)  |
|    |          |   | 1D   | 01          | 1 (base 10)   |
|    |          |   | 1E   | E6          | entry for FX1E subroutine   |
|    |          |   | 1F   | 8A          | make R(6), VX pointer, the X register   |
|    |          |   |      |             | load low order memory pointer address   |

|    |             |   |    |          |  |
|----|-------------|---|----|----------|--|
| 20 | F4 AA       | add VX, restore R(A)  | —  | —        | entry for FX55 subroutine  |
| 22 | 3B 28       | to 28 if DF is zero, no overflow, exit  | 55 | 22       | transfer variables to memory   |
| 24 | 9A FC 01    | else increment high order I address   | 56 | 86 52    | push down stack  |
| 27 | BA D4       | restore it and return   | 58 | F8 F0 A7 | load contents of R(6).0 to stack (one of F0-FF)                                      |
| —  | —           | entry for FX29 subroutine, table of display patterns is on page with interrupt routine, pointers in to table are at the beginning of the page | 5B | 07       | point R(7) to V0   |
| 29 | 91 BA       | load interrupt page address to R(A).1   | 5C | 5A       | load V0, on later entry V1, etc.   |
| 2B | 06          | load VX to D  | 5D | 87 F3    | write to M(R(A))   |
| 2C | FA 0F       | and against 0F to get least significant digit   | 5F | 17 1A    | load R(7).0 and x'or against stack byte—passed VX pointer—if result is 00 we're done |
| 2E | AA 0A AA    | get low order R(A) address from table of pointers   | 61 | 3A 5B    | increment R(7) and memory pointer  |
| 31 | D4          | return  | 63 | 12 D4    | go to 5B to transfer next VX unless done   |
| 32 | 00          | unused  | 65 | 22       | else restore stack pointer, return   |

| 5B | E2 20 A0    | restore DMA address   |
| —  | —           | DMA 4   |
| 5E | 3C 53       | continue till done  |
| 60 | 98          | R(8).1 is timer, load it (see FX07 and FX15 instructions)   |
| 61 | 32 67       | if D is zero go to 67, timer is timed out, leave alone  |
| 63 | AB 2B 8B B8 | else subtract 01 from timer, method used does not disturb the DF flag, DF is not changed by the interrupt routine |
| 67 | 88          | load R(8).0, tone duration, see FX18 instruction  |
| 68 | 32 43       | if tone duration is over go to 43   |
| 6A | 7B          | continue with or start tone   |
| 6B | 28          | decrement R(8).0, tone duration   |
| 6C | 30 44       | return, leaving tone on   |
| —  | —           | end of interpreter  |

### Extending the CHIP-8 Instruction Set

The CHIP-8 interpreter is well organized and constructed and as a result it is easy to modify and extend. If a specific task, for example the control of a robot, is to be programmed the interpretive language can be changed to suit the application. Let's look at how we might extend the current CHIP-8 instructions. There are two main types of instructions one might wish to add, those which

involve pointers to two of the CHIP-8 variables, (e.g. like 8XYN) and those which require a pointer to a single CHIP-8 variable (e.g. 6XKK).

The first group of instructions might be created by expanding either the 5XY0 instruction or the 9XY0 instruction. Say we chose to expand the 5XY0 instruction. The entry point for the 5XY0 instruction would be changed to point to a third CHIP-8 page. The least significant hex digit of the instruction would be examined and if it was 00 the instruction would have its usual meaning. However if the last hex digit was 1, 2, etc., new operations would be performed.

As an example let's expand the 5XY0 instruction to the following set:

|      |  |
|------|--|
| 5XY0 | skip if VX = VY; the next interpreter instruction is skipped over if VX equals VY (original meaning) |
| 5XY1 | skip if VX > VY; the next interpreter instruction is skipped over if VX is greater than VY           |
| 5XY2 | skip if VX < VY; the next interpreter instruction is skipped over if VX is less than VY              |
| 5XY3 | skip if VX ≠ VY; the next interpreter instruction is skipped over if VX does not equal VY            |

We will place the new subroutines in the middle of page 0E between the interrupt routine and the bottom of the CHIP-8 stack. The entry point of the new interpreter subroutine will be 0E 70 (06 70 for the 1 1/4K Elf). CHIP-8 must be modified so that the 5 instructions transfer control to this location and we shall have to place this address in the interpreter. Replace the 01 at location 00 55 with 0E (06 in the corresponding place for the 1 1/4K Elf) and replace the 98 at location 00 65 with 70.

### Additional Skip Instructions Expansion of 5XY0 Instruction

| Addr. | Code  | Notes  |
|-------|-------|--|
| 0E 70 | 93 BC | set R(C).1 to current page                         |
| 72    | 45    | load advance 2nd CHIP-8 byte, now YN               |
| 73    | FA 03 | and off 00, 01, 02, or 03 depending on instruction |
| 75    | FC 7D | add starting address of table of locations         |
| 77    | AC    | point R(C) to proper entry in table                |

|    |          |  |
|----|----------|--|
| 78 | 0C AC    | pick up table entry, point R(C) to proper subroutine address |
| 7A | 07 E6    | load VY, make R(6) the X register                            |
| 7C | DC       | go to one of four subroutines                                |
| 7D | 81       | address for 5XY0 instruction                                 |
| 7E | 8B       | address for 5XY1 instruction                                 |
| 7F | 8F       | address for 5XY2 instruction                                 |
| 80 | 87       | address for 5XY3 instruction                                 |
| —  | —        | entry for 5XY0   |
| 81 | F3       | x'or VX against VY   |
| 82 | 3A 86    | return if D does not equal 00                                |
| 84 | 15 15 D4 | else skip and return   |
| —  | —        | entry for 5XY3   |
| 87 | F3       | x'or VX against VY   |
| 88 | 3A 84    | skip if D does not equal 00                                  |
| 8A | D4       | else return  |
| —  | —        | entry for 5XY1   |
| 8B | F7       | subtract VX from VY  |
| 8C | 3B 84    | skip if DF equals zero                                       |
| 8E | D4       | else return  |
| —  | —        | entry for 5XY2   |
| 8F | F5       | subtract VY from VX  |
| 90 | 3B 84    | skip if DF equals zero                                       |
| 92 | D4       | else return, end of 5XYN subroutines                         |

Among the instructions that the interpreter lacks are simple multiply and divide instructions to go along with its addition and subtraction instructions. Let's expand the 9XY0 instruction to add these instructions to CHIP-8. Multiply and divide instructions are necessarily 16 bit ones, the product of two 8 bit numbers may be up to 16 bits long and of course we need 16 bits to represent the quotient and remainder from the division of two 8 bit numbers. An additional variable will be required to hold the most significant byte from a multiplication and the remainder from a division. VF is already a special variable and will be used to hold the most significant part of the product in multiplication and the remainder in division. As well it would be nice to be able to represent the product of a multiplication as a decimal number and a 16 bit hex to decimal conversion routine will also be added.

The new "9" instructions will be located starting at the beginning of page 0D and we shall have to change the address of the "9" instructions in the

interpreter. Memory location 00 59 should be changed from 01 to 0D and memory location 00 69 should be changed from 94 to 00.

The new instructions are:

|      |   |
|------|---|
| 9XY0 | skip if VX ≠ VY; the next interpreter instruction is skipped over if VX does not equal VY (unchanged)   |
| 9XY1 | set VF, VX equal to VX times VY where VF is the most significant part of a 16 bit word  |
| 9XY2 | set VX equal to VX divided by VY where VF is the remainder  |
| 9XY3 | let VX, VY be treated as a 16 bit word with VX the most significant part and convert to decimal; 5 decimal digits are stored at M(I), M(I + 1), M(I + 2), M(I + 3), and M(I + 4), I does not change |

#### Multiply, Divide and 16 Bit Display Instructions Expansion of 9XY0 Instruction

| Add.  | Code     | Notes  |

| 52 | F8 00 5A | set memory pointer location to 00   |    |             |   |

If one has an ASCII device connected to an ELF, perhaps a keyboard, it would be convenient to have a CHIP-8 instruction which would create symbols for the characters in ASCII code. Such an instruction is presented last, the FX94 instruction.

This instruction uses the space left unused in the interpreter by the expansion of the "5" and "9" instructions and creates symbols for the 64 characters in 6 bit ASCII. In operation it works like the FX29 instruction except that the memory pointer is set to the address of one of the 64 ASCII symbols corresponding to VX instead of to the address of one of the 16 symbols 0 - F. If the "5" and "9" instructions have not been expanded this instruction can, as well, replace the FX29 instruction and ways to implement either alternative will be given.

The instruction fits on a single page; each of the 64 ASCII symbols are coded by 3 bytes which requires 192 memory locations and the remainder of the subroutine fits in the 64 locations remaining. The construction of this instruction is quite simple. The first 16 locations on the page are patterns which are available to construct the symbols. Each ASCII symbol is designated by 5 hex digits which correspond to the patterns needed to construct the symbol. The sixth hex digit in the three words used to code each symbol serves as an indicator of the length of the symbol. When an FX94 (FX29) instruction is carried out this value is transferred to V0 where it can be used to get a pleasing spacing of the symbols.

The symbols are relatively crude, both because of the poor resolution of Elf graphics and also because they consist of combinations of only 16 patterns. However they are easily recognized and make the presentation of ASCII data relatively easy with the aid of a very simple interpreter program.

The method used to transfer control from the interpreter to the new subroutine is to change the program counter from R(3) to R(C). This change has to be done in the interpreter and the address of the new subroutine must first be loaded to R(C). If the ASCII subroutine is located on page 0C the proper entry point is 0C D0. To make an FX94 instruction add the following code to the interpreter on page 01 (4K version):

| Add.  | Code     | Notes                         |
|-------|----------|-------------------------------|
| 01 94 | F8 D0 AC | point R(C).0 to D0            |
| 97    | F8 0C BC | point R(C).1 to page 0C       |
| 9A    | DC       | make R(C) the program counter |

This code overwrites the locations which were used for the "5" and "9" instructions. The same code, but located starting at address 01 29, would change the FX29 instruction to the ASCII instruction.

### Six-Bit ASCII Symbols Subroutine

| FB | 83    | retrieve length of symbol from R(3).0               |      |      |  |
| FC | 57    | write to V0   |      |      |  |
| FD | 1A D4 | fix up R(A) and return                              |      |      |  |

The reader would probably like to see what these characters look like when displayed. Here is an interpretive program which can be used to display all of the ASCII symbols. The program waits for a switch byte (0-F) and when it is entered displays the corresponding ASCII symbol in the upper left of the screen followed by as many ASCII symbols as the screen has room for. If the byte in the interpreter (4K) at location 01 11 is changed from 0F to FF complete switch bytes (00 - FF) can be entered.

#### Program to Display ASCII Characters

| Add. | Code | Notes  |
|------|------|--|
| 0200 | F50A | V5 equals keys—waits for in button                   |
| 0202 | 6600 | V6 = 00  |
| 0204 | 6700 | V7 = 00, display pointers                            |
| 0206 | 6B3F | VB = 3F, line length                                 |
| 0208 | F594 | (F529?) set I to V5 ASCII symbol, V0 = symbol length |
| 020A | 7501 | V5 = V5 + 01   |
| 020C | D675 | display the symbol at V6, V7                         |
| 020E | 8604 | V6 = V6 + V0   |
| 0210 | 7601 | V6 = V6 + 01, space between symbols                  |
| 0212 | 8D60 | VD = V6  |
| 0214 | F594 | (F529?) set I, V0 for next symbol                    |
| 0216 | 8D04 | VD = VD + V0, add length of next symbol to VD        |
| 0218 | 8DB5 | VD = VD - VB, check will it extend past line end?    |
| 021A | 3F01 | skip if VF is 01, over the end of line               |
| 021C | 1208 | O.K. go back and display                             |
| 021E | 6600 | reset to new line                                    |
| 0220 | 7706 | V7 = V7 + 06, set line down                          |

It is hoped that these examples demonstrate the ease with which the CHIP-8 interpreter can be extended and modified. One of the limitations of CHIP-8, the fact that only memory addresses 00 00 through 0F FF are available to it, can be overcome by redesigning the interpreter to address memory in 4K fields. A field designation instruction is used to change from one 4K field to another. A relocatable 1K interpreter which includes all of the material presented in this booklet, as well as a field instruction, is listed in the Appendix. The field instruction is a four byte one which has the form, FFFF, MMMM, M is the new field and MMM is the address of the first instruction to be obeyed in the new field. For example to transfer to a new field:

| Add.  | Code | Notes                            |
|-------|------|----------------------------------|
| 0F D0 | 6300 | set V3 to 00                     |
| D2    | 6400 | set V4 to 00                     |
| D4    | 650A | set V5 to 0A                     |
| D6    | FFFF | field instruction go to field 1, |
| D8    | 1004 | 004                              |
| —     | —    |                                  |
| 10 04 | F529 | point to symbol for A            |
| 06    | D345 | display A                        |
| —     | —    | etc.                             |

More ambitious programs can be written with the 4K memory restraint removed. The field designation is stored in R(B).0 and is set on entry to the interpreter; if less than 4K of memory is available it can be ignored.

## Appendix

The interpreter listed below is relocatable and can be placed on any four contiguous pages (e.g. 0A00 - 0DFF for a 4K Elf). It *must* be entered with R(3) as the program counter. Enter at location 0000 for default values for the first interpreter instruction (01FE), the display page (0F), and the page for variables and constants (0E). To change the default values set R(5) to the address

of the first interpreter instruction, set R(B).1 to the display page, set R(6).1 to the page for variables and constants, and enter the interpreter at location 000C. The default value for the location of the first interpreter instruction (01FE) allows space for an erase display instruction (00E0) before a program which starts at location 0200. The FX94 instruction in this interpreter does not alter the value of V0.

## Notes

The FX00 and FX75 instructions cause failures when X is F because R(6) "turns" a page; R(6) should be decremented after the use of an output (64) instructions.

When using the relocatable interpreter place all the machine code subroutines in field 0 (0000 to 0FFF); they are accessible to calls from any of the 16 fields.

## Notes

Additional copies of this booklet can be ordered from:

Paul C. Moews  
16 B Yale Road  
Storrs, CT 06268

The price, \$5.50, includes first class postage and handling.  
Two other booklets with programs for the basic  $\frac{1}{4}$ K Elf are also available:

1. Music and Games
2. Graphics

for \$3 each, postpaid.
